Aviation Activity Forecasts Report

I. Purpose and Context

As a part of the FAA's ongoing National Airspace Redesign (NAR) effort, the NY/NJ/PHL Metropolitan Airspace Redesign study is investigating various alternative designs for the air traffic routes and airspace in the New York and Philadelphia Metropolitan and surrounding areas. In order to thoroughly evaluate these alternatives and meet NEPA requirements it is necessary to conduct both operational and environmental modeling of the future baseline conditions as well as each alternative. A key element in the development of accurate modeling for these conditions is the forecasting of future air traffic operational levels expected in the area and at the airports of interest. Although the FAA's office of Aviation Policy and Plans (APO) develops and regularly updates the Terminal Area Forecasts (TAF) for some 3,400 airports throughout the country, these forecasts may not undergo a rigorous forecast update for several years for a given airport. Furthermore, the TAF forecasts generally do not provide sufficient detail (aircraft type, destination, etc.) for environmental modeling. Accordingly, it was determined that an independent forecasting effort be undertaken for each of the airports evaluated in this study.

The area of interest for this study is geographically designated as the Greater New York/New Jersey/Philadelphia Metropolitan region (the "Region") including the City of New York, Long Island, New Jersey, Southern Connecticut, Eastern Pennsylvania, Philadelphia, and the northern portion of Delaware. **Exhibit 1** presents a map of the Study Area identified for this project. Because there are a large number of public and private airports that are located within this area it was necessary to undertake an evaluation process to determine the airports that would require full environmental analysis and modeling. This effort is discussed in **Section 1.6 of Chapter 1** of the EIS document. **Attachment A**, located at the end of this report, presents a listing of the airports evaluated along with some key statistics and a brief summary of the rationale for inclusion or exclusion from the study analysis. The evaluation resulted in the identification of 21 airports to be included in the study modeling. In order to provide data for the operational and environmental impacts analysis, a forecast for IFR operations in 2006 and 2011 at each of these Study airports was developed for this project. The airports in this analysis are identified in **Table 1**.

The Region is among the most congested aeronautical sectors in the National Air Space System and is expected to grow throughout the next decade as both commercial and general aviation demands compete for more airport and airspace capacity (See **Exhibit 1**). Serving as primarily a business corridor, flight frequency as opposed to aircraft gauge expansion will be an issue affecting traffic levels in the region. The purpose of the IFR forecast is to provide data input into the operational and environmental impacts analysis for both existing conditions as well as the projected levels of operations over the next decade. It will also serve as a schedule for the Total Airport and Airspace Modeler (TAAM) simulation to be conducted for the 90th percentile schedule.

The FAA sought an independent review of the FAA's Terminal Area Forecasts ("TAFs") for the Region's airports. The Region's airport forecasts from this study provide considerably more detail than TAFs including gauge and load factor assumptions of the air carriers' arriving and departing flights for the forecast benchmark years. Considerable analytical attention was also applied to the general aviation sector. In particular, the corporate aviation market is expected to grow at a more robust rate than scheduled airline service given the success and growth profile of fractional ownership programs for corporate/high end leisure aircraft.¹ The forecast for overflights or "en route" aircraft operations are also included in this document.

Table 1
Airports Included in Forecast Analysis

Airport Name	Airport Code	Type of Service
Allentown/Lehigh Valley International	ABE	Scheduled, GA, Mil, Cargo
Atlantic City International	ACY	Scheduled, GA, Mil, Cargo
Bridgeport/Igor I. Sikorsky Memorial	BDR	GA, Cargo
Caldwell/Essex County	CDW	GA
Newark Liberty International	EWR	Scheduled, GA, Cargo
Westhampton Beach/The Francis S. Gabreski	FOK	GA
Republic *	FRG	Scheduled, GA, Cargo
White Plains/Westchester County	HPN	Scheduled, GA
New Haven/Tweed-New Haven	HVN	Scheduled, GA
Wilmington/New Castle County *	ILG	GA, Mil, Cargo
Islip Long Island MacArthur	ISP	Scheduled, GA, Cargo
John F. Kennedy International	JFK	Scheduled, GA, Cargo
Linden	LDJ	GA
LaGuardia	LGA	Scheduled, GA
Morristown Municipal	MMU	GA, Cargo
Philadelphia International	PHL	Scheduled, GA, Cargo
Northeast Philadelphia Newburgh/Stewart International	PNE	GA
SWF	SWF	Scheduled, GA, Mil, Cargo
Teterboro	TEB	Scheduled, GA, Cargo
Trenton/Mercer County McGuire AFB	TTN	Scheduled, GA
	WRI	Mil

** Both Republic and New Castle have limited/occasional scheduled air service.*

All forecasts are estimates of future activity based upon assumptions about the continuation of, or changes to past air service trends. The accuracy of forecasts depends upon the accuracy of these assumptions. While past activity is not a guarantee of the course of future events, the

¹ 2000 FAA Aerospace Forecast

application of reasonable trend extrapolations do add to the confidence level in the forecast results.

II. Key Assumptions

Commercial passenger demand is projected to experience sustained growth throughout the forecast period (through 2011). International passenger activity is expected to continue to grow at a pace that exceeds the growth of U.S. Gross Domestic Product over the forecast period. Among the most pronounced changes in commercial passenger fleets in recent years has been the replacement of turboprop aircraft with regional jets. The growth in regional jet traffic has primarily been limited by the ability of the manufacturers to produce sufficient new aircraft to meet demand. The continued growth in regional jet use is expected to drive an increase in the average seating configuration of regional airline markets. A number of other general assumptions and factors affecting demand were also considered in the forecast exercise including, but not limited to, the following:

- ➔ **Aviation Security** - Passenger confidence in enhanced aviation security will return.
- ➔ **U.S. Economy** - The U.S. economy will recover beginning in the second half of 2002. Many economists believe that the recovery will be slower than from recent recessions.
- ➔ **Regional Airport Trends** - The basic character of each of the study airports will not change during the forecast period. Airports with only general aviation activity will remain GA-only airports while major facilities such as JFK, LGA, EWR, and PHL will remain the dominant airports in the region.
- ➔ **Commercial Service** - No new commercial service airports will be constructed in the region during the forecast period.
- ➔ **Airline Yield** - Airline yield will continue to decline on a constant dollar basis as projected by the FAA. The latest FAA aviation forecast predicts a 0.9 percent annual decrease in real (inflation-adjusted) U.S. domestic airline yield between 2001 and 2013. Yield is the revenue per flight mile received by the airlines for carrying each passenger. Since deregulation, the decline in real yield has accelerated, so that by 2001 real yield fell to 13.94 cents, an average yearly decline of 2.1 percent from 1978.
- ➔ **New Aircraft** - Only one new class of aircraft is assumed to be introduced throughout the forecast period. A widebody with an estimated capacity of 550 passengers is assumed to enter the international fleet in a very limited way before the end of the forecast period.
- ➔ **Adaptation of Air Carriers in a New Aviation Economy** - U.S. airlines experienced strong profits in the late 1990's, and 2000 was one of the airlines' best years in history. In 2001 however, the U. S. major airlines collectively lost over \$7 billion,

even after a governmental infusion of about \$4 billion. In 2002, the U.S. majors are expected to post losses of about \$4 billion. Due to the combined affects of the current economic recession and the events of September 11, many in the industry see more than just the swings of a cyclical business. They believe a changing of the guard may have begun. Low-fare carriers now account for nearly 20 percent of domestic air capacity, up from 6 percent in the early 1990s. Southwest has surpassed Northwest, Continental, and US Airways in terms of revenue passenger miles flown domestically.

- ➔ **Fuel Costs** - Fuel costs are a significant, yet variable, component of an airline's operating expenses. Generally, there has been an overall decline in fuel costs since 1981, which has reduced the operating costs of airlines, and therefore, the cost of air travel. In the short-term, such factors as weather, demand for heating oil, shipping incidents, political conflicts and production difficulties caused by unusual circumstances may impact fuel costs. However, these events have had little long-term effect on the overall cost of air travel. This report makes the assumption that fuel will continue to be available in sufficient quantities, that only short-term shifts will occur in the cost of fuel and that the overall trend in fuel cost increases will be moderate during the forecast period. It is also assumed that the new fuel-efficient aircraft will moderate the impact of long-term fluctuations in fuel costs and that fuel costs will not significantly impact long-term average ticket prices. Therefore, it is assumed that air travel demand will not be adversely impacted by fuel costs or availability over the forecast period.
- ➔ **Long-term Economic Indicators** - A basic assumption inherent in any forecast of aviation demand is the overall condition of the U.S. and world economies. Long-term, continued economic stability, reasonable consumer confidence, and growth of disposable personal income are foreseen by most economists. All are positive influences on future air travel growth.
- ➔ **Teleconferencing** - Industry observers have considered the impacts of communications technology on air travel demand. No reliable empirical evidence has surfaced to date that quantifies the impact of technology on air travel demand. Therefore, it is assumed that air travel demand will not be adversely impacted by teleconferencing during the forecast period.
- ➔ **Hub-and-Spoke Effects** - Airlines have always concentrated air service at a limited number of airports, usually in major cities. Since airline deregulation in 1978, there has been an even more pronounced emphasis on developing hub and spoke route systems centered on a limited number of airports. The hub and spoke route networks offer the most economically efficient system to move passengers and cargo throughout the country. For most international service, using hubs as gateways is almost the only way to provide the economies of scale sufficient to operate long-range, high capacity aircraft across the Atlantic, Pacific or to other distant international destinations. No significant change in the hub-and-spoke system is foreseen in the forecast period. However, new routes and new service points will

continually be developed as markets expand and as new carriers appear, new marketing niches develop and other events affect the travel market.

- ➔ **Re-regulation of Air Carriers** - Passenger airlines were first released from federal regulation in 1978 with regard to domestic route selection, fare levels, and certain other operating conditions. Air cargo carriers were also de-regulated in the same time period after aggressive lobbying by FedEx. Since 1978, numerous airline bankruptcies have resulted in carrier consolidation and the emergence of dominant market share situations at numerous airports, resulted in layoffs and other employment issues, and raised questions about safety that have been blamed on deregulation, creating some pressure in Washington to re-regulate the airline industry. Re-regulation of airlines is conceivable, but it is assumed in this forecast to be unlikely.
- ➔ **Hypersonic Aircraft** - Like the new large aircraft, new hypersonic aircraft, capable of crossing the Pacific in only a few hours, are being discussed by both airlines and aircraft manufacturers. These could be updated, longer-range versions of the Concorde now operating across the Atlantic or an entirely new vehicle. For hypersonic aircraft to become a reality, technical, environmental and economic hurdles must be overcome. No aircraft manufacturer has yet committed to such an undertaking. However, it is doubtful a hypersonic aircraft could be designed, built and introduced to service until after the end of the forecast period. Consequently, the impact of hypersonic aircraft during the forecast period was not considered.

III. Sources

The forecasting process requires thorough and detailed baseline data. The first task involved the assembly of all necessary data to develop the forecast model for the 21 airports. Data sources used for the regional passengers and operations forecasts included the following:

- ➔ **Official Airline Guide (“OAG”), October 31, 2000** – For scheduled airline service, historical aircraft, seat configurations, frequency, and city-pairs among other metrics were culled and analyzed. For each airport with scheduled airline service, a 10-year city-pair add-drop matrix was developed. An add-drop matrix illustrates how air carriers at a particular station provide a predictable pattern of air service depending on whether that station is a hub [i.e., Philadelphia International (“PHL”)] or a spoke [i.e., MacArthur-Islip (“ISP”)]. The add-drop matrix informs the analysts about future new city pairs and frequencies going forward. In addition, the OAG data provides key aircraft gauge (i.e., average aircraft size) trends, although it should be noted the AIR 21 reversed the aircraft gauge trends at LaGuardia (“LGA”). Although, aircraft gauge had been steadily increasing at LGA, AIR 21 (Congressional legislation passed in 1999) lifted the high density rule and allowed increased flight frequency at LGA. Carriers responded to AIR-21 by scheduling an increase in regional jet activity. **Table 2** shows an example of an add-drop matrix for 6 markets indicating the year in which the market is dropped with a “-1” and the year in which a market is added with a “1”.

Table 2							
Sample Add & Drop Matrix							
Destination	1995	1996	1997	1998	1999	2000	2001
Allentown, PA (ABE)	-1	1	-1			1	
Albuquerque, NM (ABQ)		-1				1	
Acapulco, MEX (ACA)		1				-1	
Nantucket, MA (ACK)			-1				1
Atlantic City, NJ (ACY)				-1			1
Bader Field, NJ (AIY)	1		-1			1	

- ➔ **U.S. Department of Transportation 10% Ticket Survey (O&D Data), 1990-2000** – Passenger Origin & Destination (“O&D”) data provide a wealth of airline specific data for all domestic markets served at the Region’s airports. The database examined average load factors and average yield. Again, these historical measures provide important clues into how air carriers may sustain, expand or reduce air service in select airport markets within the study area.
- ➔ **Terminal Area Forecasts (TAF), 2001-2015** – The most recent TAFs, published in December of 2001, were downloaded from the FAA website and modified in format for ease of analysis. In addition, the airline yield trends and projections necessary for demand forecasting were provided by the FAA. Yield is a key proxy variable for the price of air travel and a critical part of any aviation demand forecast equation.
- ➔ **J. P. Fleets, 2001-2002** – Projected airline aircraft orders and options were provided by J.P. Fleets, a vendor that specializes in providing this data. Fleet forecasts provide insight into gauge assumptions and aircraft engine types (a critical variable for noise analysis).
- ➔ **Woods & Poole, 1990-2015** – Socio-economic data including population, per capita income, employment and earnings were provided by Woods & Poole. Woods & Poole is an independent vendor and nationally recognized firm that provides expert economic and demographic analysis.
- ➔ **Airframe Manufacturers Forecast, 2000** – Boeing, Airbus and Bombarier all provide their own forecasts of aircraft, passengers and revenue passenger miles. These reports were examined for comparability purposes.
- ➔ **Enhanced Traffic Management System (ETMS), January/November 2000** – provides FAA radar data including aircraft, airlines, flight paths and flight times for air traffic that filed IFR flight plans only.

- ➔ **Collection and Analysis of Terminal Records (CATERLOG), 2000** – provides similar data as ETMS for those airports operated by the Port Authority of NY & NJ including John F. Kennedy (“JFK”), Newark (“EWR”), and LGA airports for calendar year 2000.
- ➔ **Internet** – A good deal of data was culled from various internet sights mostly relating to corporate aviation and fractional ownership companies.
- ➔ **Airport Statistics²** – Data were requested from selected airports on annual operations and passengers as well as connecting rates and other airline statistics.
- ➔ **Airport Staff Interviews** – Select in-person or telephone interviews were conducted to query airport operators about current market conditions, airline strategies, demand trends and development plans. Among the airports interviewed were: JFK, LGA, EWR, Teterboro Airport (“TEB”), Stewart Airport (“SWF”), ISP and Westchester County Airport (“HPN”).

IV. Passenger and Operations Forecasts

This section presents the approach, methodologies and results of the regional passenger and operations forecasts for the 21 airports. All forecasts were prepared for the future years of interest; 2006 and 2011. **Exhibit 2** presents an overview of the forecasting methodology employed for this analysis in a flow chart form.

The forecasting effort culminated in the development of detailed operational schedules for each of the study airports for each future year. Because the operational modeling (airspace simulation) and the environmental modeling (noise modeling) focus on different issues, they require different operational scenarios for their analysis. In order to ensure that a given airspace/route design is sufficiently robust to accommodate a typical busy day of traffic, the airspace simulation effort analyzes the 90th-percentile (90-P) day, or 37th busiest day of traffic at the facility of interest. For the noise analysis, however; the FAA requires the evaluation to be based on the average annual day (AAD) of operations in the year of interest. This forecasting effort provides both an AAD and a 90-P schedule for each airport of interest in the study area.

Table 3 presents the forecast profile for each of the airports in the study resulting from the analysis. These profiles generally identify the expected role of the airport in the future and provide a summary of key issues affecting the expected future activity at each airport.

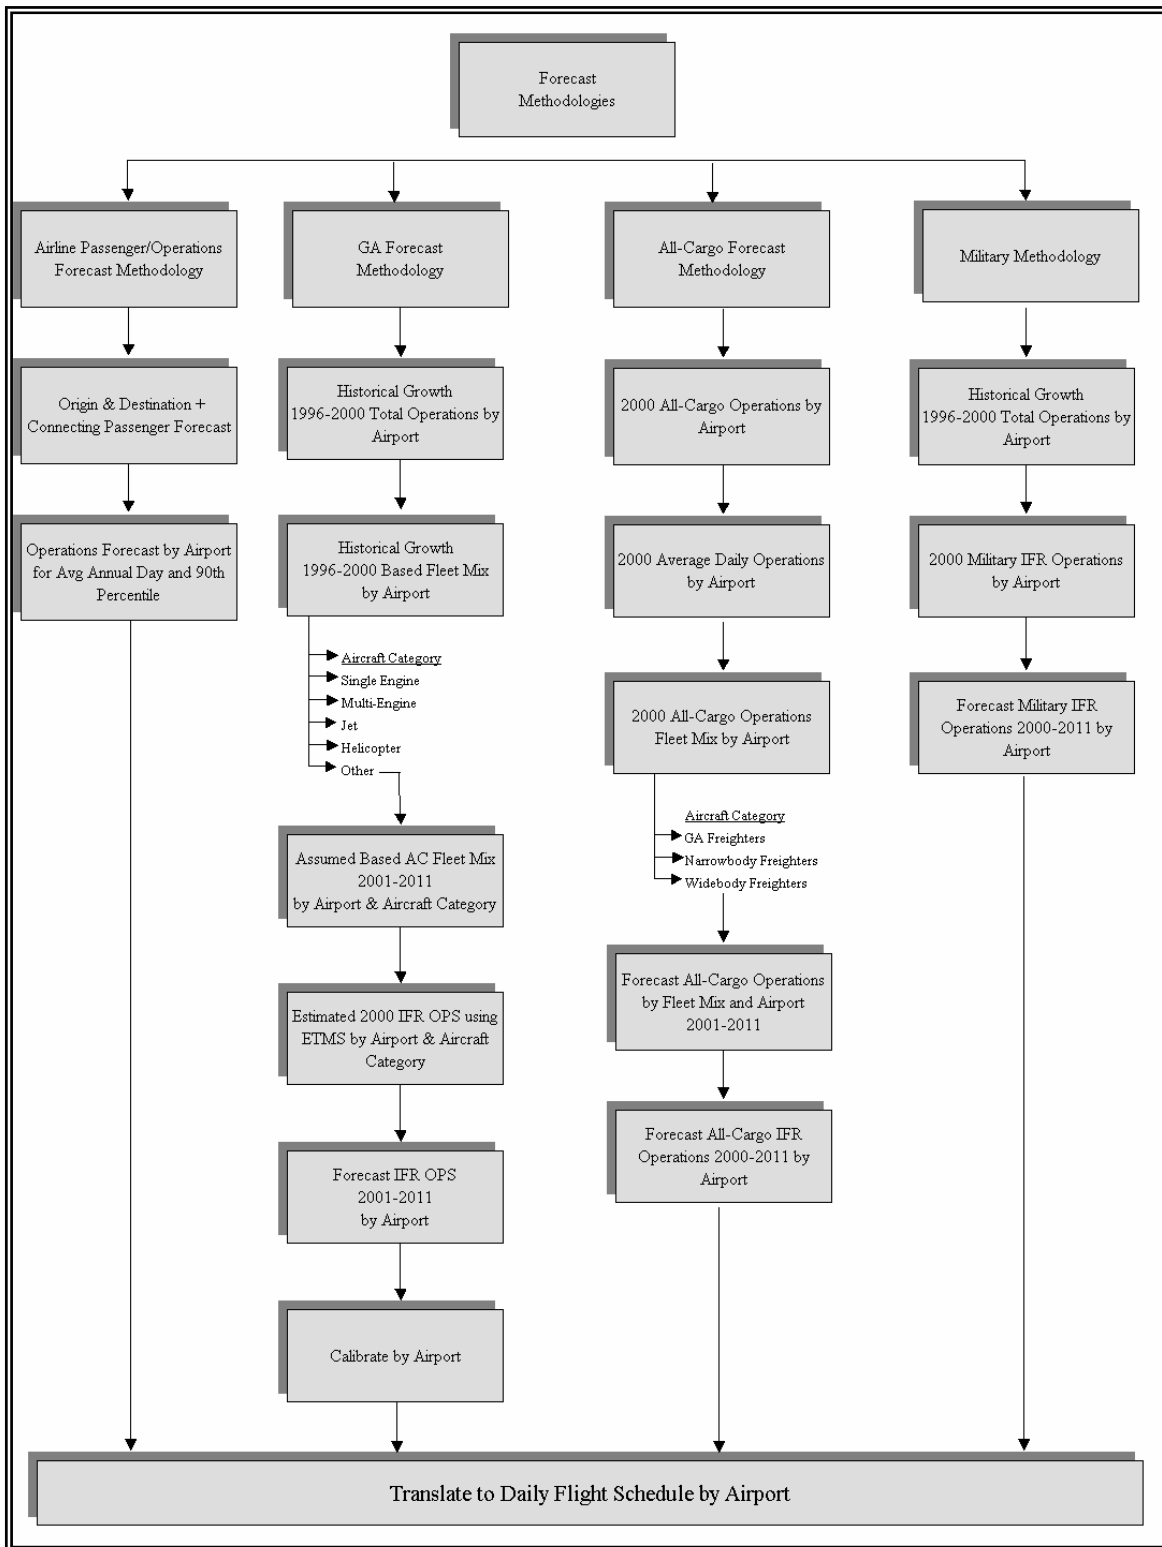

Exhibit 2
General Forecasting Methodology

Table 3 Forecast Analysis - Airport Profiles			
Class/Airport	2006	2011	Observations
Large Hub			
EWR	Continental mega-hub; airfield constraints	Continued hub maturation; increased gauge	
JFK	jetBlue sustains and expands operations, American completes terminal (+27 gates)	Delta expands domestic and international operations; incremental growth	
LGA	Congestion pricing/other solution implemented	Increasing gauge/load factors	
PHL	Remains a viable air carrier hub	Remains a viable air carrier hub	
Regional			
ABE	Incremental spoke service growth, Some upgauging of aircraft	Incremental Spoke Service Growth, Some Upgauging of Aircraft, No low fare operator	<i>May benefit in long term from metro sprawl; good eastern (NJ) access</i>
ACY	Low incremental spoke service growth, Some upgauging of aircraft	Low incremental spoke service growth, Some upgauging of aircraft	<i>Largely surface mode destination Military maintains operations</i>
HPN	Low incremental spoke service growth, Robust GA activity	Low incremental spoke service growth, Limited upgauging of aircraft	<i>Highly constrained facilities; local operating restrictions will remain in place</i>
ISP	Incremental spoke service growth, Limited expansion by WN	Incremental spoke service growth, Limited expansion by WN	<i>Facility constraints will remain in place</i>
SWF	Incremental spoke service growth, Some upgauging of aircraft and GA activity	Incremental spoke service growth, Introduction of WN spoke	<i>New GE corporate aircraft base; ANG maintains operations; will benefit from metro sprawl</i>
HVN	Low incremental spoke service growth	Low incremental spoke service growth	
Reliever			
CDW	Remains robust corporate facility	Remains robust corporate facility	
LDJ	Remains GA reliever to EWR	Remains GA reliever to EWR	
WRI	Active AFB	Active AFB	
MMU	Increased corporate activity	Increased corporate activity	<i>Major GA reliever to EWR; Bizjet potential</i>
IGL	Remains GA reliever to PHL	Remains GA reliever to PHL	<i>Has not sustained scheduled air service</i>
PNE	Remains GA reliever to PHL	Remains GA reliever to PHL	
FRG	Remains GA reliever to LGA/JFK	Remains GA reliever to LGA/JFK	<i>Has not sustained scheduled air service</i>
BDR	Remains GA reliever	Remains GA reliever	
FOK	GA field for eastern Long Island	GA field for eastern Long Island	<i>ANG Search & Rescue units maintained</i>
TEB	Remains robust corporate facility	Remains robust corporate facility	<i>Bizjet and air charter restrictions intended</i>
TTN	Limited regional service	Limited regional service	

IV-A. Passenger Forecasts

Air transportation demand is derived from the demographic and economic profile of a region. Origin & Destination (O&D) passengers are those passengers who arrive at or depart from the airport of interest; they do not change aircraft at the subject airport. The total number of O&D passengers is a reflection of a region's attractiveness as a place in which to live, visit, work, and conduct business. O&D passengers include both resident and non-resident air travelers.

The forecast employed regression analysis, a methodology that has been successfully used and accepted by most major airports and the FAA. A regression equation describes the mathematical relationship between two sets of variables referred to as the "dependent" and the "independent" variables. For example, in the case of aviation activity, the dependent variable is the annual number of passengers. The independent variable(s) are those economic and demographic drivers that generate passenger demand such as population, employment and airline ticket prices.

Historical O&D passenger data (the dependent variable) was paired against population, employment, per capita personal income, and domestic yield (the independent variables) to establish a statistical relationship between the demographic and economic variables and the demand for air travel among the 11 airports with commercial air service.

With this mathematical relationship (the regression equation) established, the forecasts of demographic variables were combined with airline yield data to project future levels of O&D passengers.

Following the O&D passenger projections, estimated connecting passenger activity was "layered" on to the O&D passenger volumes to derive total passenger volumes for each airport. In cases where airline-specific hub activity is expected to remain stable, industry analysts typically hold connecting passenger volumes constant as a result of long-term industry-wide historical trends. Consequently, the connecting passenger volumes at the major airports in this study were assumed to remain constant over the forecast horizon at or about current levels. Connecting passengers are present at only the large hub airports in the area, including JFK, EWR, LGA, and PHL. After developing the passenger forecasts for each airport in the study region using the bottom-up approach described above, the individual forecasts were compared to the FAA's Terminal Area Forecast (TAF) as an order-of-magnitude check. **Table 4** presents the enplanement forecasts for the 11 study area airports that have air carrier service.

Generally, the new passenger forecasts were well within 10 percent of the TAF levels. The weighted average variance for total operations and the aggregate TAFs passenger forecasts for 2006 is less than 1 percent. The weighted average variance in 2011 from the TAF is less than 2 percent. The FAA uses a 10 percent threshold as a rule-of-thumb for accepting non-FAA forecasts as the basis for planning and environmental studies. For SWF, the forecast included the introduction of new low-fare service (as previously noted) that was not anticipated in the TAF. The FAA's 2000 TAF forecast for Trenton (TTN) overstated enplanement levels due to the mid-year withdrawal of service by Westwind Airlines. The FAA was briefed on this variance from the TAF and accepted the reasoning and results.

Table 4
Passenger Forecast Summary & TAF Comparison

	2000 Enplanements			2006 Enplanements			2011 Enplanements		
	Forecast	FAA TAF	% Diff	Forecast	FAA TAF	% Diff	Forecast	FAA TAF	% Diff
ABE	478,758	473,849	1.0%	545,912	535,219	2.0%	600,359	586,361	2.3%
ACY	462,055	468,718	-1.4%	516,208	514,815	0.3%	565,408	553,229	2.2%
EWR	17,542,172	17,273,978	1.5%	21,041,615	21,494,456	-2.2%	24,270,685	25,011,523	-3.1%

IV-B. Operations Forecasts

After developing the passenger forecasts for the region, airport-specific operations forecasts were developed for airline, general aviation, freighter and military operations. Based on the annual operations forecast, two sets of operational schedules were developed for each airport: Average Annual Day (“AAD”) and 90th Percentile (“90P”) day schedules. The 90P schedule is essentially a representation of the 37th busiest day of the year for the study airports. This is reflective of a moderately busy day of air traffic that is often used for analysis of airport and air traffic systems. The AAD forecast is used for environmental planning purposes, while the 90P is more commonly used for operational planning purposes. For each airport, the AAD and 90P forecast schedules were developed for the baseline year of 2000 and the forecast years of 2006 and 2011. These forecast schedules included daily and annual operations for airline, general aviation, freighter and military IFR operations components.

The approach and methodology for each forecast component is outlined below.

- ➔ **Airline Operations Forecasts** – For each airport with scheduled airline service, current average day airline schedules for Friday, October 13, 2000, were culled from the OAG. This baseline schedule was then calibrated by applying average historical load factors. These schedules were then annualized so that they reflected near actual annual volumes.

1. Adding Frequencies – Insofar as air carriers add and drop city pairs and frequencies, analysts performed a similar exercise building from the baseline schedule. By analyzing air service trends, they added new flights to markets at the appropriate time of day where demand warranted. For example, in 2006 it can be expected that Southwest Airlines would have additional departures from ISP to its East Coast focus city at Baltimore/Washington International Airport (“BWI”). Therefore, the 2006 schedule would reflect this increased service at an average Southwest load factor. This exercise was repeated (and tested) for every airline and every airport with commercial air service. This “bottom-up” approach containing increased scheduled activity also enables analysts to provide considerable detail including aircraft and engine types for environmental analysis.
2. Dropping Frequencies – If the data, combined with industry trends, indicated that a particular city pair would not likely be sustainable by 2006 and 2011, that service would be dropped. There are several noticeable examples, including the unlikely sustainability of the Atlantic City (“ACY”)-PHL city pair served by a US Airways regional affiliate. Data has suggested that ACY is a market served mainly by passengers traveling in automobiles and buses, especially from locations within a radius of 250 miles.
3. Change of Gauge – A review of airline fleet mix and fleet orders/options indicated that certain city pairs served by specific carriers would potentially increase (or decrease) the size of deployed aircraft. For example, the Boeing 737-800 as a replacement aircraft for earlier models has considerably more seat capacity (depending on carrier and configuration). In addition, the new Airbus A380 [New Large Aircraft (“NLA”)] was assumed to serve JFK within the forecast horizon (i.e., included in 2011 JFK schedules).
4. New Entrants – Over the planning horizon, select airports and select new entrants were included. In addition to the likely introduction of a number of international carriers (primarily at JFK, PHL and EWR), the expansion in the region of two low-fare carriers, in particular, was modeled. The successful commencement of service and aggressive growth by jetBlue Airways at JFK was developed. The commencement and a modest expansion of service by Southwest at ISP were also modeled. Also, it was assumed that Southwest Airlines (or an equivalent low-fare operator) would commence service to SWF by 2011. The airport operator and analysts have sound reason to believe that such an event would occur in the forecast horizon.

Each arrival and departure flight was linked (matched) based on the applicable average ground time requirement for each city pair, the type of flight (domestic/international), type of equipment (widebody/narrowbody/regional), and particular carrier.

- ➔ **General Aviation Operations Forecasts** – For each airport, a general aviation (GA) IFR operations forecast was developed. The approach to GA included analysis and observations regarding the types of aircraft used based on the FAA categorization of GA aircraft including single engine piston, multi-engine piston, turbo prop, jet, helicopter and experimental aircraft types. Each of these aircraft types has different growth profiles. The FAA’s projected growth in each aircraft type was applied to the based-aircraft fleet at each airport. For example, the FAA and industry observers expect that the jet component in the GA market will grow at or about 4 percent per annum over the forecast horizon.³ If a particular airport has a large percentage of based and itinerant aircraft that are jets (i.e., HPN, TEB), the FAA jet growth rate was also applied to the single/multiple piston activity. It was further assumed that most single engine and multi-engine piston aircraft were VFR operations, and thus not part of the IFR operations forecast. If a particular airport exhibited historically a large percentage of local operations and was known to have flight schools, a much lower IFR rate was applied (e.g., FRG). All jet (corporate) operations at all airports were assumed to be IFR flight activity. Helicopter and experimental aircraft were assumed to be VFR-only operations, and were therefore excluded from the IFR projections.
- ➔ **Freighter Operations Forecasts** – All cargo or freighter operations were examined on an airport-specific basis. Known hubs for express/integrator carriers like FedEx at Newark or UPS at PHL were individually evaluated for the forecast of operations and fleet mix. Other airports with limited freighter operations (i.e., check runners at TEB) were extrapolated by trend analysis. All freighter operations were assumed as IFR only.
- ➔ **Military Operations Forecasts**– Many of the airports in the Region handle a combination of tactical, strategic and helicopter operations conducted by the military. Because future military operations projections are difficult to forecast, analysts relied on FAA military projections for each airport. It should be noted that all military helicopter operations were assumed as VFR while all military jet operations were assumed as IFR in nature.
- ➔ **Overflight Operations Forecast** – Overflight operations were examined as congestion also occurs with aircraft bypassing this busy airspace on approach to other airports in the vicinity or “en route” to more distant destinations. For the purposes of this analysis this category of operations is defined as IFR flight planned traffic that neither traverses some portion of the study area, is below 14,000 feet MSL altitude, and neither originates ore is destined anywhere within the study area. Overflight projections were derived with the aid of the FAA En route forecast contained in the 2000 FAA Aerospace Forecast.

V. Forecast Results – IFR Operations

Annual operations and aircraft fleet mix information were compiled for Overflights and each of the 21 airports in the study based on the methodologies and analysis presented in the previous sections. **Table 5** presents a summary of the forecast annual IFR operations level for each airport and for the study area overflights. In general, continued operational growth is expected at most of the study airports as well as with the overflights of the study area. With the exception of LGA, IFR operations at the major (JFK, EWR, PHL, TAB) airports in the study are expected to initially grow in double digits through 2006. This operational growth is expected to continue at a reduced pace between 2006 and 2011. At LGA, modest initial operational growth is expected through 2006 followed by a plateau through 2011 due to airfield constraints.

Table 5
Forecast Summary
Study Area Annual IFR Flight Operations

Identifier	Airport	2000	2006	2011
LGA	La Guardia	387,995	416,465	416,465
JFK	John F. Kennedy International	347,115	413,910	451,505

Total		2,688,225	3,147,065	3,412,795

Source: Landrum & Brown Analysis, 2001

Overall, IFR traffic in the Study Area (including overflights) is expected to grow some 17 percent by 2006 to 3.15M annual operations. This growth is expected to continue at a reduced rate resulting in some 3.41M annual operations by 2011. This is a 27 percent increase over the baseline 2000 conditions. While the overall future operational growth is largely driven

by increased aviation demand in the form of passengers and corporate aviation, the operational numbers are intensified by changes in the future fleet mix. Among the most pronounced changes in commercial passenger fleets in the late 1990's has been the replacement of turboprop aircraft with regional jets. This trend toward the use of regional jets has continued in recent years with many major airlines replacing narrow body aircraft with regional jets in search of more profitable operations. While this "down-gauging" of aircraft results higher efficiency and profits for the airlines, it takes more flights to serve the same number of passengers. Thus, operational levels increase while accommodating the same number of passengers as before.

Table 6 presents a generalized fleet mix summary for each forecast year by study airport. As the table indicates, the IFR operational fleet mix in the study area is expected to gradually transition to a higher proportion of jets throughout the planning horizon. Currently, just over 70 percent of the IFR operations in the study area are conducted by jet aircraft. This is expected to increase to 86 percent by 2006 and 92 percent by 2011. The percentage of operations conducted by piston engine aircraft operations is expected to stay relatively flat at the 2.5 to 3 percent that is currently seen. Thus, the majority of the shift to jet operations comes from the turbo-prop category. Detailed fleet mix tables for each airport in the study are presented in **Attachment B** at the end of this appendix.

Table 6

VI The Impact of the Events of September 11 on Forecast Task

The bulk of this forecast effort was conducted before the events of September 11, 2001. Given the relatively long forecast horizon, 2001-2011, any short-term suppression of aviation demand is expected to recover by the first benchmark year of 2006. Outlined below are some observations that support the position that aviation growth will rebound over the forecast horizon.

As the aviation industry struggles with reduced traffic and a shaken confidence in aviation security resulting from the events of September 11, most industry stakeholders are searching for some comparable system shock in an effort to estimate the short- and long-term impacts on aggregate aviation demand. In the post-September 11 world, industry stakeholders wonder whether aviation activity will return to the sustainable and even healthy levels to which airport operators had grown accustomed. There is no comparable event to what occurred on September 11. However, when analysts look back over the last 40 years and examine aviation traffic in light of an impressive listing of system shocks, reason for optimism is not unfounded. The 1960s led with the Cuban Missile Crisis, while the 1970s introduced aircraft hijackings and their effect on international aviation demand in particular. The 1980s opened with the PATCO strike, while the Persian Gulf War created temporary travel uncertainty in the early 1990s. The new millennium brings us a new war against worldwide terrorism that presents its unique set of uncertainties. If aviation history provides any guidance, this downturn will be offset by a pronounced recovery. As illustrated below, sharp recoils have been followed by discernable recoveries.

It should be noted that every aforementioned decade-defining industry episode was adjoined by an economic recession. The rash of hijackings in the mid-1970s was concurrent with OPEC actions and economic hardship in the United States and abroad. Months before the Reagan Administration replaced civilian air traffic controllers with military controllers; the nation was well into a deep and debilitating recession. The Persian Gulf War was prosecuted as economic malaise gripped the nation. An economic recession was also well underway before the events of September 11. Economic recessions have always been the industry's single greatest threat to profitability, competition and traffic volumes. Provided that confidence in aviation security returns, an industry rebound will likely occur as previously observed.

The industry's capacity and congestion debate has been temporarily sidelined as air carriers have slashed their schedules by as much as 20 percent or more in some markets. However, capacity and congestion relief is believed to be temporary. Those same forces of supply and demand that threatened the efficiency of the nation's air transportation system prior to September 11 will re-emerge at severely constrained airports including two subject airports – Newark and LaGuardia.

Therefore, for the purposes of this forecast task, both the events of September 11 and the current economic conditions are considered short-term and are not expected to affect long-term demand at the subject airports.
